NEW SPECIES OF BRACHIOPODS FROM THE
UPPER DEVONIAN OF HAY RIVER,
WESTERN CANADA

by A. E. H. PEDDER

ABSTRACT. Nervostrophia borealis, N. maclarenii, and Cyrina lapidea are described and figured as new species from the Hay River formation of the North West Territories, Canada. Dunwillowella crackingi is described and figured as a new species from the lower Grumblber formation of the same area. All the fossils are of Fossiliferous age.

The fossils described were collected by Dr. P. E. Kent of BP Exploration (Canada) Limited and by Dr. E. W. Best, R. L. Pemberton, and A. E. H. Pedder of Triad Oil Co. Ltd. in June 1958. The author is much indebted to these companies for permission to publish the work and to present the type specimens to the Geological Survey of Canada.

Biostratigraphy. Stratigraphical thicknesses in the Hay River area have mostly been obtained from scattered incomplete river sections and various published estimates differ considerably. Warren and Stelck (1950, p. 68) gave the thickness of the type Hay River formation (as later restricted by Crickmay) as about 270 feet; Crickmay’s figure for the same interval is 630 feet (1957, p. 6). Farmilo is quoted by Law (1955, p. 177) as having measured about 900 feet of Hay River shale on Hay River and deWit (unpublished) has obtained for Triad Oil Co. Ltd. a total thickness of 1,250 feet for the Hay River shales. Both of these latter measurements include Crickmay’s Simpson formation, but, even so, indicate a thickness in excess of 630 feet for the type Hay River formation (restricted). Bore-hole evidence (Law 1955, fig. 5) also indicates a greater thickness than quoted by Crickmay.

The new species were obtained from three beds. The lowest is a grey argillaceous limestone grading to a pure coquina bed in part, and is exposed on Hay River opposite mile 14 of the Mackenzie Highway (Grimshaw Road). Part of its fauna is: Elia sophora sp., Hederella sp., Orbiculoidea sp., Productella sp., Nervostrophia borealis sp. nov., Monelasminia besti Pedder, Schizophoria sp., Atropa sp., Spinitrypa sp., Eusteroskalma reidfordi Crickmay, Cyrtospirifer [→ Regelia] glauceus Crickmay, Cyrina lapidea sp. nov., Spinarbix sp., Tentaculites mackenzieanus Kindle, ostracodes, and a trilobite. The horizon is the lowest assigned to the Hay River formation as restricted by Crickmay.

The second bed is a limestone exposed just above Louise Falls on Hay River. Stratigraphically it is immediately below the topmost shale and siltstone of the Hay River formation and is currently regarded as being from 30 to 40 feet below the top of that formation. The rock is very fossiliferous, but only those specimens exposed are easily collected and those generally water worn. Part of the fauna is: Macquea protea Smith, Nervostrophia maculati sp. nov., Productella sp., Atropa sp., Cyrtospirifer sp., Adolphia sp., pelecypods, Tentaculites sp., Devonocidaris sp., and Decadocrinus sp.

The highest bed is a maroon argillaceous limestone exposed on Hay River opposite mile 38 of the Mackenzie Highway. It is near the base of the Grumblber formation and
the following is part of the bed's fauna: Clionoides sp., Spongophyllum imperfectum
Smith, Autocoilus sp., Thamnophora sp., Vinelloidea sp., Leptotrypeia sp., Hedercilla sp.,
Hermodia sp., Petrocraza sp., Stryphnoidea sp., Dowilliaella? crickmayi sp. nov.,
Schuchertia sp., Strophoidea sp., Gypidula sp., Atrypa rubromitra Crickmay, A. spp.,
Cynostrigir sp., Tentocirrus sp., Adolphi sp., Cystina sp., Crapeae sp., pelecypods,
cephalopods, Cornulites sp., Spiorbis angulosus Fenton and Fenton, crinoid fragments.

Non Dowilliaella variabilis Calvin sp.

Name derivation. Latin, borealis = northern.

Types. Holotype, specimen originally Triad Oil Co. Ltd. collection no. X46c, now Geological Survey
of Canada type no. 14,598. Six paratypes, specimens originally Triad Oil Co. Ltd. collection nos.
X46f-k, now Geological Survey of Canada type nos. 14,599 to 14,604.

Type stratum. Hay River formation, coquina bed 630 feet below top (Crickmay 1957, p. 6; not 1953,
p. 11); Upper Devonian, Frasian.

Type locality. Canada, North West Territories, Hay River opposite mile 14 of the Mackenzie Highway
measured south-westward, about 80 feet above water-level and 10 feet below bank top. Latitude 60° 41'
N., longitude 115° 54' W.

Description. Shell small and fragile. Profile plano-convex. Outline semicircular anteriorly,
posteriorly just flexed at pedicle beak, cardinal extremities with small mucrones, postero-
lateral margins weakly concave. Anterior commissure rectimarginate. Shell substance
very thin, calcite and pseudopunctate.

Pedicle valve weak convex centrally and postero-centrally, plane near lateral and
anterior margins. Umbonal region, small, longer than broad and only slightly elevated.
Beak minute and blunt. Beak ridges sharp along entire length. Interarea plane, apsa-
cinal, very broadly equilaterally triangular with an apical angle of about 168°.
Delthyrium open anteriorly, closed posteriorly by a strongly medianly arched pseudodelthy-
dium. Hinge-line straight, denticulate along most of its length in young valves and for
about two-thirds of its length in adults. Process pits deep as thin shell permits, slightly
posteriorly directed. Ventral process low and narrow. Muscle scars petal-shaped, about
one-half as long as the valve, lightly impressed, bounded postero-laterally by heavy
ridges, open antero-laterally and anteriorly. Adductor and diductor scars not differenti-
ated in the type specimens. Median septum very fine, about one-half the length of the
musscle scars. Interior surface, with the exception of the muscle scars and cardinalia,
entirely and finely papillose; postero-lateral muscle bounding ridges less finely papillose.
External surface ornament variable, of more or less continuous, generally straight, rarely sinuous costae, separated by from one to four intercalated costellae; costellae rare in gerontic specimens; costae and costellae number about seven per millimetre near margins of valve. Concentric micro-fila superimposed on entire surface, numbering about fifteen per millimetre. Interarea with growth striae parallel to hinge-line and with clear traces of denticles, especially anteriorly.

Brachial valve plane. Umbo and beak not developed. Interarea linear. Notothyrium displaced by cardinalia. Chilidium degenerate. Hinge-line straight, socketed opposite denticles of pedicle valve. Cardinal process lobes, stout, disjunct, with attachment faces posteriorly directed. Socket plates small, attached to and parallel to cardinal process lobes. Muscle scars subtriangular, lightly impressed, bounded postero-laterally by large hummocks divergent 90° to each other, open anteriorly; each muscle divided anteriorly by low, broad, elongate elevations parallel to postero-lateral muscle ridges. Median septum broad posteriorly, rapidly tapered to a fine ridge anteriorly, three-fourths the length of the valve. Interior surface, with the exception of the cardinalia and deeper parts of muscle scars, finely and irregularly papillate; postero-lateral muscle ridges and elevations in anterior part of muscles less finely papillate; exterior ornament similar to that of pedicle valve, but costae less developed and approaching the size of the costellae. Denticles sockets visible from exterior through a thin shell layer.

Dimensions (partly reconstructed and estimated from the contour of the concentric micro fila). Holotype, paratypes 2, 4 (pedicle valves), and 5 (brachial valve), length 11.4, 5.1, 5.4, and 5.0 mm., width 14.0, 8.0, 8.3, and 6.6 mm., depth 1.3, 1.1, and 0.1 (not including depth of process lobes) mm.

Remarks. No similar fossil has been named from the Upper Devonian. The species superficially resembles Desmallinarian variabilis (Calvin) from the Independence formation of Iowa, but is not congeneric with it.

*Nereostrophia maclaireni* sp. nov.

Plate 36, figs. 1-5

Types. Holotype, specimen originally Triad Oil Co. Ltd. collection no. X38s, now Geological Survey of Canada type no. 14,605. Three paratypes, specimens originally Triad Oil Co. Ltd. collection nos. X38t-v, now Geological Survey of Canada type nos. 14,606 to 14,608.

Type stratum. Hay River formation, upper unnamed siltstone, shale, and limestone unit, 30 to 40 feet below the top of the formation (Crickmey, 1957, p. 6; not 1953, p. 11); Upper Devonian, Frasnian.

Type locality. Canada, North West Territories, a few feet above Louise Falls on Hay River. Latitude 60° 30' N, longitude 116° 14' W.

Hinge line denticulate for about 75 per cent. of its length. Process pits shallow. Nature of cardinalia and musculature not revealed in the primary material. Internal ornament centrally finely and closely papillose with traces of the external ornament visible near the margins. External ornament of continuous, straight, or slightly sinuous costae developed from costellae, latter number from two to nine, generally five, between each costae; costae and costellae number about six per millimetre near the margins of the valve. Fine concentric micro-fila superimposed on most, if not all, the surface.

Brachial valve plane. Umbo not developed. Beak represented by a minute projection of the base of the cardinal process. Notothyrium displaced by cardinalia. Childium probably degenerate. Hinge-line socketed opposite the denticles of the pedicle valve. Cardinal process lobes not well preserved in type material, disjunct, with attachment faces posteriorly directed. Socket plates larger than average relative size for the genus, attached to and divergent from, the cardinal process lobes. Muscle scars small, petal-shaped, superficial, bounded postero-laterally by large crescent-shaped hummocks, open in other directions. Median septum degenerate. Postero-lateral muscle bounding hummocks strongly papillose, other parts of the interior surface not markedly papillose, external ornament visible from the interior near the valve margins. External ornament similar to that of the pedicle valve. Denticle sockets visible from the exterior through a very thin shell layer.

**Dimensions.** Holotype and paratype 3, length 20.0 and 13.5 mm., width (less mucrones) 26.8 and 25.0 mm. (with mucrones)? and 36.0 mm. depth (pedicle valve only) 1.5 and 1.2 mm.

**Remarks.** In several respects this species is not typical of *Nervostrophia*. The shell is exceptionally thin and delicate, a median septum is scarcely developed in the brachial valve; the relatively large, divergent socket plates and unimpressed muscle scars of the brachial valve are also exceptional for the genus.

From *Nervostrophia calvini* Stainbrook, occurring in the Independence formation of Iowa, this species is distinguished by its lack of a strong geniculation near the anterior and antero-lateral commissure and also, perhaps, by internal details, which have not been illustrated for *N. calvini*.

From *N. vestita* Crickmay, occurring lower in the Hay River formation on Hay River, this species is distinguished by its shorter median septum and postero-lateral muscle bounding ridges in the pedicle valve and by its less nervous surface ornament.

**Genus Douvillina** Spriestersbach 1926 emended Williams 1953

*Genoholotype* (by monotypy) *Douvillina filifer* Schmidt 1913, pp. 313, 314, pl. 23, figs. 1a–7. *Cetra- jugans* zone (Cuvianian, or lower Middle Devonian), südlich der Attendorn-Elper Doppelmühle, Germany.

**Remarks.** Spriestersbach proposed *Douvillina* as a subgenus of *Stropheodonta*, differing from that genus by possession of brace plates (Stützplatten) and in having concave ventral and convex dorsal valves instead of convex ventral and concave dorsal valves. The species described below is associated with *Douvillina* only because it is a resupinate *Douvillina*-like stropheodontid. It is possibly not congeneric with *Douvillina filifer* Schmidt.
PALAEOLOGY, VOLUME 3
Dowilla? crickmaya sp. nov.
Plate 36, figs. 7–11; text-fig. 1n

Name derivation. Patronym for Dr. C. H. Crickmaya, Imperial Oil Ltd., Calgary, Alberta.

Type stratum. Grumblar formation, maroon argillaceous limestone about 80 feet above the base of the formation, uppermost Prannian.

Type locality. Canada, North West Territories, Hay River opposite mile 38 of the Mackenzie Highway (Grinshaw Road), measured south-westward. Latitude 60° 29' N., longitude 116° 19' W.

Description. Shell small and robust. Profile very gently resupinate, concavo-convex immediately anterior of hinge, convexi-plane or just convexi-concave centrally, biconvex near anterior margin (text-fig. 1n). Outline semicircular anteriorly, posterolateral margins nearly straight, cardinal extremities with small mucrones. Anterior commissure rectimarginate. Shell substance relatively thick, calcitic and pseudopunctate.

Pedicle valve almost plane, very gently convex umbonally, plane or just concave centrally, very gently convex near anterior and lateral margins. Umbonal region feebly developed. Beak minute, projecting only very slightly. Beak ridges sharp along entire length. Inter-area plane, apsaclinal, subrectangular. Delthyrium equilaterally triangular with an

TEXT-FIG. 1. a–m, *Cyrtites lapidea* sp. nov., Hay River formation coquina bed, Hay River opposite mile 14 of the Mackenzie Highway, North West Territories, Canada, paratype 4 (now destroyed), series of sections of pedicle valve, ×10, measurements above each figure indicate distance from beak. 

*n, Dovillinella? crickmayi* sp. nov., diagrammatic but based on holotype and paratypes, longitudinal section, ×5.
apical angle of about 12°, entirely closed by a completely and strongly arched pseudodeltidium. Hinge-line straight, denticulate along entire length. Process pits deep, slightly posteriorly directed. Ventral process robust, anteriorly prolonged to a fine low median ridge, extending to the anterior edge of the muscle scars. Muscle scars prominent, elevated to the form of a saucer, posterior edge at a variable angle of about 20° with the hinge-line, anterior edge parallel with hinge-line, lateral margins rounded, more sharply so laterally than anteriorly. Interior surface, apart from the muscle scars and cardinalia, finely and evenly papillose; cardinalia smooth, muscle scars with faint radial striations. External ornament of fine, variable, primary and intercalated costae of different sizes, numbering about six per millimetre at the posterolateral margins and about four per millimetre at the anterior margin of adult valves. Growth lines strong, but developed only near the margins of some valves. Interearea smooth with faint traces of denticles visible anteriorly.

Brachial valve generally very slightly concave immediately anterior of the central part of the hinge-line, gently convex elsewhere (text-fig. 1n). Outline similar to that of the pedicle valve, but less or not mucronate. Umbo and beak not developed. Interearea apsaclinal and almost linear. Notothyrium displaced by cardinalia. Chilidium vestigial, gently convex. Hinge-line straight, socketed opposite the denticles of the pedicle valve. Cardinal process lobes of average size, disjunct, with attachment faces posteriorly directed. Muscle scars asymmetrically petal-shaped with long narrow extensions parallel to and laterally adjacent posteriorly, to the brace plates, deeply impressed. Median septum broad, relatively low, anteriorly bifurcated, bifurcated parts confluent with the elongated brace plates. Interior surface of cardinalia smooth, muscle scars without papillae, but irregularly pitted, rest of central part of surface finely and evenly papillose, valve borders with clear traces of surface costae. Exterior surface ornament same as that of pedicle valve with denticle sockets visible through a very thin shell layer.

Dimensions. Holotype (dissociated pedicle valve) and paratype 4 (dissociated brachial valve), length 12·1 and 11·8 mm., width 14·1 and 15·5 mm., depth 19·9 and 18·8 mm.

Remarks. Strophonella does not occur in the Grumber formation. Warren and Stelck (1950, p. 67) were probably referring to this species, since it is common in the lower Grumber maroon beds, while other resupinate strophoedoontids are either rare or absent. No similar species has been named.

of Canada type no. 14,614. Three preserved paratypes, specimens originally Triad Oil Co. Ltd. collection nos. X46n–0, now Geological Survey of Canada type nos. 14,125 to 14,617. Fourth paratype, specimen originally Triad Oil Co. Ltd. collection no. X46p, subsequently destroyed for serial sectioning.

Type stratum. Hay River formation (equina bed 630 feet below top (Crickmay 1957, p. 6; not 1933 p. 11); Upper Devonian, Frasnian.

Type locality. Canada, North West Territories, Hay River opposite mile 14 of the Mackenzie Highway (Grimshaw Road) measured south-westward, about 80 feet above water-level and 10 feet below bank top. Latitude 60° 41’ N., longitude 115° 54’ W.

Description. Shell small, subpyramidal, generally slightly asymmetrical rarely strongly asymmetrical or symmetrical. Profile subtriangular. Outline nearly semicircular. Hingeline 95–100 per cent. of total shell width, just flexed centrally. Cardinal extremities abruptly rounded or minutely mucronate. Anterior commissure uniplicate. Shell substance moderately thick, calcitic, finely and closely endopunctate.

Pedicle valve subpyramidal, weakly convex along posterior midline, almost straight, but steeply inclined anteriorly; lateral slopes only very gently convex but steeply inclined. Sulcus with origin at beak, shallow, gently concave transversely, produced to a short semicircular tongue. Umbonal region not differentiated. Beak blunt, just projecting, straight. Beak ridges variable, either sharp or rounded. Interarea equilaterally triangular, orthoclinal, or proclinal and plane surfaced towards hinge, apascinal and concave towards beak, apical angle about 90°. Delthyrium with an apical angle of about 26°, closed near hinge by an arched pseudodeltidium. Foramen triangular towards beak, semi-elliptical towards pseudodeltidium, long axis four-fifths of the length of the delthyrium. Hinge teeth tear-shaped in section, of moderate size. Dental plates ankylosed to median septum in posterior 1-5 mm., of valve, withdrawn forming a spondylum from 1-5 to 3-2 mm. from beak tip, gradually reduced anteriorly, disappearing about 5-7 mm. from beak tip. Median septum high and produced to a tichohirum in posterior 3-2 mm., gradually reduced anteriorly. Muscle scars not seen in primary material.

Brachial valve weakly convex. Fold transversely convex posteriorly, flat-topped anteriorly, low, elevated only in anterior three-fifths of adult valve. Umbonal region and beak not differentiated. Interarea linear. Hinge-plate well developed about the sockets and socket plates, divided by a median ridge. Sockets large, bounded internally by, and partly excavated into, strong socket plates, divergent to each other at 90°. Cardinal process bilobed, smooth. Spiralia not preserved in primary material, attachment confluent with the anterior parts of both the socket and hinge plates. Median septum extremely low and fine, absent in anterior two-fifths of valve.

Ornamented by from 5 to 8, typically 7, costae on the pedicle valve and by from 4 to 7, typically 6, on the brachial valve; costae rounded and progressively diminished laterally. Sulcus smooth. Fold smooth or with very weak anterior median furrow. Interarea with vertical striae. Growth lines irregular, mostly very fine and crowded, especially on the interarea, but gerontic specimens may bear coarser growth lines near the commissure. Abundant fine endopunctae clearly visible on shell surface, except on the interarea.

Dimensions. Holotypes and paratypes 1 to 3, length 4-7, 5-3, 5-2, and 6-4 mm., width 7-7, 7-0, 6-6, and 8-0 mm., depth 5-4, 5-1 (both valves), 1-1 and 1-8 (brachial valves only) mm.

Distinctions. From C. induta Stainbrook, occurring in the Independence formation of Iowa, this species is distinguished by its smaller (× 1/2) average size, finer costae, less
developed sulcus and tongue and by the absence of a micro-ornament of fine radial granulose ridges described on *C. imulta*. The internal structure of *C. imulta* is undescribed in literature; there may be, therefore, further distinctions between the two species.
