A REVIEW OF THE MESOZOIC OSTRACOD GENUS
PROGONOCYHERE AND ITS CLOSE ALLIES

by R. C. WHATLEY and S. BALLENT

ABSTRACT. The cytheracean ostracod genus Progonocyhere and its immediate allies in the Jurassic and Cretaceous are reviewed. All known species of 12 genera are considered. Only five of these genera (Dromacythere, Fastigacythere, Glyphocythere, Majungaella, Progonocythere) remain valid; the seven rejected genera are Amicytheridea, Glyptogacythere, Malzia, Novocythere, Strictocythere, Tickalarucythere and Zerqacythere. We consider that the level of validity among other cytheracean groups is probably similar and that this reflects a serious decline in taxonomic standards based upon the inability of many authors to discriminate between generic and specific characters. The simple philosophy that differences of kind are generic, while those of degree are specific, seems to be largely ignored by many present day ostracod workers. We advocate that, wherever possible, the diagnoses of existing genera be expanded to embrace end-members, rather than the continual creation of so many superfluous generic taxa based on specific characters, which will eventually render the science inoperable.

UNFORTUNATELY, a very large number of ostracod genera erected in the past 25 years or so have been discriminated on the basis of what the present authors consider to be specific characters. The senior author, in preparing various families of the Cytheracea for the revision of the Treatise on invertebrate palaeontology, Part Q, Ostracoda of which he is coordinating author, has been struck by the very large number of monotypic, or near monotypic, genera erected on extremely flimsy evidence. Any species with the slightest morphological divergence from the norm of a genus is immediately denominated as new, notwithstanding that it may be the sole representative of that taxon. The more logical procedure, of regarding such newly discovered species as new morphological end members of an existing plexus of species is rarely adopted. Some of the prolific creators of such spurious taxa are possibly of the opinion that the original diagnosis of a genus is sacrosanct and immutable when, in fact, it must inevitably be expanded as new species are encountered. In the production of the Treatise revision, a large number of new, ornate podocopid genera of various families have been subsumed as junior synonyms within pre-existing genera by the simple and logical expedient of emending the diagnosis of pre-existing genera.

It is almost always taxa with prominent ornamentation which are associated with this form of generic ‘splitting’. Smooth ostracods, always difficult to deal with taxonomically, are much more stable generically. In many cases, it seems that authors do not understand the differences between what are primary and secondary aspects of ostracod ornament. For example, if ten or so species of a genus all have the same primary ornament, (say) of three parallel ribs, then to encounter a species similar in all other respects but with only two ribs or with four, is possibly to have found something worthy of separate generic status. However, if all of those ten species are, in their intercostal areas, differently ornamented (this being a secondary feature), these differences are important specific characters and no more. All too often, authors have used such secondary ornamentation to create new genera and complicate, almost beyond function, the existing taxonomic system. One needs only to look at the near total anarchy which exists in the Foraminiferida, with hundreds of monotypic genera, to know that this is a practice which should be suppressed.

To work in taxonomy is to exercise judgement and not to try to break records. If authors were to apply the philosophy that differences of kind were generic, while those of degree were specific, then a much more rational system would prevail.

In the following study, we examine 12 Mesozoic podocopinid cytheracean ostracod genera of the family Progonocytheridae Sylvester-Bradley, most closely related in their morphology to the genus Progonocythere Sylvester-Bradley (Table 1). We find that seven are readily referable to other genera within the complex and that only five are valid. This, of course, is a matter of judgement. However, we have in the course of this study, examined and considered all of the species attributed to each of the original 12 genera. Sad to relate, in many areas of the Treatise revision, approximately the same percentage of validity seems to obtain!

### TABLE 1. The twelve genera of Progonocytheridae considered here, arranged in date order, with type species and geographical distribution. The five genera considered to be valid are in italics.

THE GENERA

In the Treatise revision, the Progonocytheridae will comprise only genera with entomodont/lobodont hinges (sensu Moore and Pitrat 1961; non Van Morkhoven 1962). The family will be divided into the Progonocytherinae, comprising subovate to subtriangular genera with a convex
dorsal margin and more or less strong ventro-lateral tumidity, similar to those discussed here, and another subfamily which will embrace subrectangular to subquadrate genera. The latter group comprises such genera as *Acanthocythere* Sylvester-Bradley, 1956, *Afrocytheridea* Bate, 1975, *Lophocythere* Sylvester-Bradley, 1948, *Neurocythere* Whatley, 1970, *Terquemula* Blaszyk and Malz, 1965, and *Trichordis* Grekoff, 1963. These are the subject of a subsequent review by the authors which is in preparation.

In order to facilitate comparison between them, the most important morphological characters of the 12 genera included in the present study, are outlined in Table 2; those which we consider to be valid are in italics.

**Progonocythere** Sylvester Bradley, 1948

This genus was based initially on three species: *Cythere blakeana* Jones, 1884, *C. juglandica* Jones, 1884 and *Progonocythere stilla*, the last named being a new species chosen by Sylvester-Bradley as the type. All these species had the 'hinge characteristics of the subfamily': a straight hinge composed of three elements, anterior, posterior and median, in which the median element is further subdivided into antero-median and postero-median parts. In the larger (left) valve, the anterior and posterior elements are short, loculate sockets; the median element is a bar, the anterior portion of which is always dentate, the posterior portion being denticulate. In the smaller (right) valve, the anterior and posterior elements are short dentate bars, the anterior always, the posterior usually, denticulate. The median element is clearly divided into an expanded anterior groove with four or five distinct loculi, and a posterior groove narrower than the anterior, with more numerous but less clearly defined locellae. The above description of the entomodont hinge is modified from Sylvester-Bradley (1948, p. 189).

Whatley (1964) reviewed the status of the genus and indicated that some species added since 1948 were better accommodated elsewhere. Forms with antimerodont rather than entomodont hinges in particular were excluded. Some of the species rejected from the genus by Whatley (1964) have subsequently been described as new genera, e.g. *Progonocythere hieroglyphica* Swain and Peterson is now assigned to *Pseudoperissocytheridea* Mandelstam (see Whatley 1970, p. 351).

In the present review, we have encountered numerous species placed in *Progonocythere*, mostly since 1964, which we consider would be best removed from the genus and accommodated elsewhere. These are listed below (in date order of first citation of combination) together with two of Sylvester-Bradley's (1948) original three species which have been transferred since 1964.

1. *Progonocythere juglandica* (Jones, 1884) in Sylvester-Bradley 1948 (pl. 12, figs 5–6), from the Middle Jurassic of Europe and Madagascar was assigned to *Fastigatocythere* by Wienholz (1967).
2. *Progonocythere blakeana* (Jones, 1884) in Sylvester-Bradley 1948 (pl. 12, figs 3–4), from the Middle Jurassic of Europe, is assigned to *Terquemula* Blaszyk and Malz following Bate (1969, p. 393) who designated, discussed and illustrated the lectotype.
4. *Progonocythere? bemelenensis* (Veen) and *Progonocythere subcarinata* (Bosquet) in Howe and Laurencich 1958, p. 470, from the Maastrichtian of South Limburg, Holland, are both *Brachocythere* Alexander.
5. *Progonocythere* sp. A, Wall, 1960 (pl. 28, figs 12–14), from the Callovian of Saskatchewan, Canada, resembles *Glyptocythere* Brand and Malz, but its hinge is antimerodont and it should be removed from the *Progonocytheridae*.
6. *Progonocythere juglandica* (Jones) subs. *malgachica* Grekoff, 1963 (pl. 3, figs 56–62; pl. 8, fig. 216), *P. accessa* Grekoff, 1963 (pl. 3, figs 63–68), *P. bicornuata* Grekoff, 1963 (pl. 3, figs 69–76; pl. 8, figs 218–221), *P. bejotakaensis* Grekoff, 1963 (pl. 3, figs 77–80; pl. 8, figs 215, 217) and *Progonocythere* 2393 Grekoff, 1963 (pl. 4, figs 105–108), all from the Bathonian and Callovian of Madagascar, were assigned by Wienholz (1967) to *Fastigatocythere*.
### TABLE 2. The 12 genera of Prognoicytherinae considered here, giving author, date of publication, number of species and details of size and most important morphological characters. Valid taxa are written in bold.

</tbody>
</table>
7. Progonocythere salkula Grekoff, 1963 (pl. 4, figs 88–91), from the Middle Callovian of Madagascar, probably belongs in Fastigatocythere Wienholz because of its triangular and posteriorly acuminate shape and post-ocular sulcus.
8. Progonocythere mundula Grekoff, 1963 (pl. 4, figs 92–95), from the Middle Callovian of Madagascar, certainly belongs in Majungaella Grekoff.
9. Progonocythere? juglandica (Jones) sensu Oertli 1963 (pl. 28, fig. 2b), from the Bathonian of France, certainly belongs in Fastigatocythere Wienholz.
10. Progonocythere? aff. anoda Peterson subspp. ancestor (Oertli) in Maync, 1966 (pl. 10, fig. 48), from the Bathonian of Israel, belongs in Fastigatocythere Wienholz (= F. bakeri (Basha) sensu Rosenfeld et al. 1987, pl. 3, figs 1–8).
11. Progonocythere? posteriorhumulis Blaszyk, 1967 (pl. 20, figs 11–13; text-fig. 20) from the Middle Bathonian of Poland, seems to have an antimerodont hinge and is much too elongate-acuminate posteriorly to be Progonocythere. In shape, it resembles Aaleniella Plumhoff.
12. Progonocythere (Majungaella) nematis Dingle in Dingle and Klinger, 1972 (pl. 18, fig. a), from the Upper Jurassic of South Africa, belongs in Majungaella Grekoff.
13. Progonocythere (Majungaella) bretonensis Dingle in Dingle and Klinger, 1972 (fig. 4; pl. 16, figs f–i; pl. 17, figs a–c), from the Upper Jurassic of South Africa, belongs in neither Progonocythere nor Majungaella, which we regard as discrete taxa. This species belongs in Fastigatocythere Wienholz, because of its triangular and posteriorly acuminate shape, its post-ocular sulcus and (although weakly developed) its inverted chevron ornament.
14. A. Progonocythere (Majungaella) reticulata Dingle in Dingle and Klinger, 1972 (pl. 17, figs d–i) (non Progonocythere reticulata Bate, 1963 which is a true Progonocythere) is from the Upper Jurassic of South Africa. From its shape and outline, we consider it to belong in Afrocycatidea Bate.
15. Progonocythere spinitensis Jain and Mannikeri, 1975 (pl. 1, figs f–h), from the Upper Jurassic of India, certainly belongs in Majungaella Grekoff.
16. Progonocythere befothaensis (sic) Grekoff sensu Guha (1976, pl. 2, figs 12a–b, 13), from the Upper Jurassic of Kutch, India, belongs in Fastigatocythere Wienholz.
17. Progonocythere plettbenbergenis McLachlan, Brenner and McMillan, 1976 (pl. 16, figs 3–7), from the Haurtivian of well PB-A/1 (South Africa), belongs in Fastigatocythere Wienholz.
18. ? Progonocythere sp. A McLachlan et al., 1976 (pl. 16, figs 8–10), from the ?Berrisanian–Lower Valanginian of well PB-A/1 (South Africa), belongs in Fastigatocythere Wienholz.
19. Progonocythere reticulata Dingle et al., 1976 (pl. 16, figs 1–2), from the Valanginian of well PB-A/1 (South Africa), should be included in Afrocycatidea Bate.
20. Progonocythere bretonensis Dingle et al., 1976 (pl. 15, figs 18–21), from the Valanginian of well PB-A/1 well (South Africa), belongs in Fastigatocythere Wienholz.
21. Progonocythere neupragnensis Musacchio, 1978 (pl. 2, figs 14–18), from the Middle Callovian of Argentina, could, by its shape and outline, be tentatively included in Fastigatocythere Wienholz.
22. Progonocythere cf. reticulata Dingle sensu Musacchio, 1981 (pl. 2, fig. 12), from the Valanginian of Argentina, is similar to and possibly conspecific with Dingle’s species above and is, therefore, considered to belong in Afrocycatidea Bate.
23. Progonocythere pyramidica, P. ramosa and P. schuleriformis Wasfi, El Sweify and Abdelmalik, 1982 (pl. 5, respectively figs 54–55, figs 46–48 and fig. 37), from the Bathonian and Callovian of the Gulf of Suez, Egypt, do not belong in Progonocythere but are placed, tentatively (due to poor descriptions and illustrations) in Fastigatocythere Wienholz (pyramidica, ramosa) and Galliacyctheridea Oertli (schuleriformis).
24. Progonocythere A Kiellbowicz et al., 1983 (pl. 6, fig. 12) is from the Valanginian of the Argentine part of the Austral Basin (southern Argentina). According to the illustrations (there is no description), it does not belong to Progonocythere; its clearly triangular outline and strong ventral rib suggest that it should be tentatively included in Fastigatocythere Wienholz.
25. Progonocythere? freundi Rosenfeld and Raab, 1984 (pl. 9, figs 10–16), from the Neocomian of Israel, is much too elongate and acuminate posteriorly. It also has a chevron-type ornament which is not typical of Progonocythere, and could possibly be included in Neocycatidea Mertens.
26. Progonocythere implicata Ljubimova and Mohan in Kulshresht et al., 1985 (fig. 7.11–7.12), from the Callovian–Oxfordian of India, more closely resembles Afrocycatidea Bate.
27. Progonocythere banniensis Neale and Singh, 1985 (pl. 3, fig. 2), from the Callovian of India, more closely resembles Afrocycatidea Bate.

Doubtful species of Progonocythere. Progonocythere retusa Grekoff, 1963, from the Middle
Bathonian of Madagascar, has, according to the author, chevron-type ornament. Since this feature is not visible in the illustrations (pl. 3, figs 81–87) and the lateral surface is smooth with isolated punctuation, we have provisionally retained this species in *Progonocythere* despite the fact that it is rather elongate, although not so elongate as species such as *P. polonica* Blaszyk.

*Progonocythere* cf. *letruelensis* (Rohr, 1976) in Malz et al. 1985 (pl. 6, fig. 57), from the Bajocian–Callovian of Sardinia, seems to be too strongly tumid to belong in *Progonocythere*; it may belong in *Klieana* Martin.

*Progonocythere* sp. Rosenfeld et al. 1987 (pl. 3, fig. 11), from the Oxfordian of Israel and *Progonocythere* *kutchensis* Guha, 1976 (pl. 1, figs 2a–b, 3), from the Upper Jurassic of India, are doubtful species due to their incomplete description and poor illustration.

**Synonymized genera.** We consider that the genus *Malzia* Bate, 1965 (p. 110, pl. 9, figs 5–8; pl. 10, figs 1–3), from the British Bajocian, is merely *Progonocythere* with a ventro-lateral keel-like prolongation, similar to that of *Progonocythere* *yonshabensis* Bate, 1965 (pl. 12, figs 5–14; pl. 13, figs 1–4) from the Bajocian of the Grey Limestone Series [= Scarborough Formation], Yorkshire. Similarly, we regard *Strictocythere* Sheppard in Brand, 1990 (p. 207, pl. 13, figs 8–15), from the Upper Bathonian of Europe, as merely a more elongate-oval *Progonocythere*. We have emended the diagnosis of *Progonocythere* to include the species of these synonymized genera.

**Emended diagnosis of Progonocythere Sylvester-Bradley, 1948.** Progonocytherinae with ovate to elongate-ovate, subrectangular or subquadrate shape; ventro-laterally tumid; with or without ventro-lateral keel-like prolongations extending below the ventral surface; smooth, punctate to pitted and weakly reticulate; ventral surface with longitudinal ribs, often shallow vertical median sulci. Eye swelling and post-ocular sulcus present in some species. Entomodont hinge with accommodation groove in left valve in some species. Anterior pore canals usually eight but ranging to 16. Muscle scars comprising vertical or curved row of four adductors and heart or oval shaped frontal scar; usually one mandibular but two reported for some species. Left valve larger than right. Sexually dimorphic; males longer, less high and less tumid than females.

**Distribution.** *Progonocythere* ranges from the Bajocian to Oxfordian, although Bate (1977, p. 234) cited a species from the Kimeridgian of Spain. It has a geographical range largely restricted to the Northern Hemisphere, particularly Britain and Europe. Ascoli (1988, p. 25) recorded, but did not illustrate, *P. polonica* and *P. aff. rugosa* from the Bathonian of offshore eastern Canada. Two species, *P. laeviscula* and *P. prolongata* [Ex *Strictocythere*], from the Callovian–Oxfordian of India and Madagascar, and the Bajocian of Australia respectively, are known Southern Hemisphere species.

**Valid species.** We consider the following species (listed in date order) to be valid members of *Progonocythere*. In this, and all subsequent lists of valid species, an asterisk indicates a new combination:

*P. stilla* Sylvester-Bradley, 1948; Bathonian, Britain (Pl. 1, figs 1–3)
*P. polonica* Blaszyk, 1959; Bathonian Poland (Ex *Strictocythere* (Text-fig. 11–1))
*P. ogrodzienicensis* Blaszyk, 1959; Bathonian, Poland
*P. laeviscula* Ljubimova, Guha and Mohan, 1960; Callovian–Oxfordian, India
*P. cristata* Bate, 1963; Bajocian, Britain
*P. reticulata* Bate, 1963; Bajocian, Britain
*P. multipunctata* Whatley, 1964; Oxfordian, Britain
*P. parastilla* Whatley, 1964; Oxfordian, Britain
*P. acuminata* Bate, 1965; Bajocian, Britain
*P. biconcina* (Bate, 1965); Upper Bajocian, England (Ex *Malzia*) (Pl. 1, figs 8–9)
*P. polita* Bate, 1965; Bajocian, Britain
*P. unica* (Bate, 1965); Upper Bajocian, England (Ex *Malzia*)
Glyptocythere Brand and Malz, 1962

This genus was described by Brand and Malz (1962) based on six species (type species Glyptocythere tuberodentina) with entomodont hinge and egg-shaped to trapezoidal valves in lateral view, strongly inflated lateral surface and an ornament with or without strong reticulation, and vertical ribs or only

EXPLANATION OF PLATE 1

Figs 1–3. Progonocythere stilla Sylvester-Bradley; Bathonian, Langton Herring, Dorset, England; The Natural History Museum, Department of Palaeontology. 1–2, 41908, holotype; right valve. 1, external view. 2, internal view. 3, paratype, 41909, external view. All × 64.

Figs 4–6. Glyptocythere tuberodentina Brand and Malz; Bajocian, Germany; Senckenberg Museum, Department of Palaeontology, Frankfurt-am-Main. 4, SMF Xe 4299, holotype; female, left valve, external view. 5, SMF Xe 4306, paratype; female, right valve, internal view. 6, SMF Xe 4306; female, right valve, external view. All × 50.

Fig. 7. Majungaelia perforata Grekoff; Portlandian, Madagascar; Laboratoire de Paléontologie, Muséum National d'Histoire Naturelle, Paris; H275, holotype; female, right valve, external view; × 54.

Figs 8–9. Progonocythere bicornata (Bate) (Ex Malizia); Upper Bajocian, Berkshire, England; The Natural History Museum, Department of Palaeontology; Io 1797; female, left valve. 8, external view. 9, dorsal view. Both × 59.

Figs 10–14. Fastigatocythere juglandica (Jones) (Ex Progonocythere Whatley; Ex Cythere Jones), Upper Bajocian, Oxfordshire. Aberystwyth Micropalaeontological Museum. 10, RCW/Bath/107; female, left valve, external view. 11, RCW/Bath/105; female, right valve, external view. 12, RCW/Bath/109; male, right valve, external view. 13, RCW/Bath/107; female, left valve, internal view. 14, RCW/Bath/102; male, left valve, external view. All × 57.

Figs 15–16. Majungaelia santaeucriziana (Rossi de García, 1972) (Ex Novocythere); Aptian–Albian, southern Argentina; toptype from collections of Dirección Nacional Servicio Geológico, Buenos Aires, and now in micropalaeontological collections of Division de Paleozoología Invertebrados, Museo de La Plata, La Plata, Argentina. From type level, borehole Sc-1, at 903–918m, Santa Cruz, Argentina; MLP 0271; female, left valve. 15, external view. 16, internal view. Both × 47.

Fig. 17. Fastigatocythere ihopenys (Grekoff, 1963) (Ex Amicytheridea Bate; Ex Procytheridea Grekoff); Middle Callovian, Tanzania. The Natural History Museum, Department of Palaeontology; Io 6251; female, left valve, external view; × 70.

Figs 18–20. Fastigatocythere triangulata (Bate, 1975) (Ex Amicytheridea); Callovian, Tanzania; The Natural History Museum, Department of Palaeontology. 18, Io 6116; male, right valve, external view. 19, Io 6115; male, right valve, internal view. × 64. 19, Io 6115; male, right valve, external view. × 85. 20, Io 6114; female, left valve, external view. × 69.
WHATLEY and BALLENT, Mesozoic ostracods
low swellings. In 1966, they reviewed the genus and added 16 new species. It was considered to be typical of the Bajocian and Bathonian, with a geographical distribution extending from Britain, south-eastwards to the Ukraine (Pemjakova 1970) and Uzbekistan (Masumov 1973, see *Macrodenitina aspera*, pl. 9, fig. 2).

We consider that the following taxa are best removed from the genus and accommodated elsewhere:

1. *Glyptocythere polita* Bate, 1965 (pl. 5, figs 8–11; pl. 6, figs 1–9), from the Bajocian of Britain, closely resembles *Progonocythere* in shape and in its smooth shell surface, with shallow median sulcus, and its convex ventrolateral extension of the carapace like a thin keel. We have included this species in *Progonocythere* although we are well aware that end members of the two genera are morphologically very similar and that convergence between the two is likely.

2. *Glyptocythere juglandica* (Jones) Bate, 1967 (pl. 4, fig. 9), from the Bathonian of Britain, is now *Fastigatocythere* Wienholz.

3. *Glyptocythere? malzi* Dépêche, 1973 (pl. 2, figs 9–13), from the Bathonian of France, was later considered by her to be *Kinkelinella* Martin, 1960 (see Dépêche 1985, pl. 30, fig. 15); we agree.

5. *Glyptocythere?* sp. Malz et al., 1985 (pl. 6, figs 6–8), from the Bathonian of north-west Sardinia, and only figured, more closely resembles *Progonocythere*.

6. *Glyptocythere oblonga* (Basha) sensu Rosenfeld and Gerry in Rosenfeld et al. 1987 (pl. 4, figs 7–8), from the Bajocian–Bathonian of Israel, should be included in *Fastigatocythere* Wienholz.

*Diagnosis of Glyptocythere* *Brand and Malz*, 1962. At present, we do not regard it as necessary to amend the original diagnosis of the genus except to ensure that it includes rather elongate species such as *G. guembeliana* (Jones) in which the ornament is very feeble or almost smooth. A translated synopsis of the original diagnosis is given below.

Carapace medium to large, egg-shaped to trapezoidal in lateral view; subrectangular to elliptical in dorsal view with end marginal borders clearly distinct from strongly inflated lateral surface. Left valve larger than right valve. Dorsal margin medially vaulted in left valve, overhung by dorso-lateral surface. Ocular features absent. Ornament with or without strong reticulation with separate longitudinal and vertical ribs or low swellings. Avestibulate. Marginal area wide. Usually nine but up to 12 radial pore canals anteriorly, straight, widely spaced and unbranched; three to five posteriorly. Normal pore canals tend to open through elevations in ornament. Hinge entomodont.

*Valid species.* We consider the following species to be valid members of *Glyptocythere*:

*G. auricula* Brand and Malz, 1962; Bathonian, Germany
*G. dorsiocostata* Brand and Malz, 1962; Bajocian, Germany
*G. rudimenta* Brand and Malz, 1962; Bajocian, Germany
*G. tenusulcata* Brand and Malz, 1962; Bajocian, Germany
*G. tuberodentina* Brand and Malz, 1962; Bajocian, Germany (Pl. 1, figs 4–6)
*G. tuberosa* Brand and Malz, 1962; Bathonian, Germany
*G. costata* Bate, 1965; Bajocian, Britain
*G. scitula* Bate, 1965; Bajocian–Bathonian, Britain
*G. comes* Brand and Malz, 1966; Bathonian, Germany
*G. concentrica* Brand and Malz, 1966; Bajocian, Germany
*G. hieroglyphica* Brand and Malz, 1966; Bajocian, Germany
*G. interreite* Brand and Malz, 1966; Bajocian, Germany
*G. meandrica* Brand and Malz, 1966; Bajocian, Germany
*G. perpolita* Brand and Malz, 1966; Bajocian, Germany
*G. plicata* Brand and Malz, 1966; Bajocian, Germany
*G. praecursor* Brand and Malz, 1966; Bajocian, Germany
*G. regulariformis* Brand and Malz, 1966; Bajocian, Germany
*G. rugosa* Brand and Malz, 1966; Bajocian, Germany
**G. similis** Brand and Malz, 1966; Bajocian–Bathonian, Germany

**G. sowerbyi** Brand and Malz, 1966; Bajocian, Germany.

**G. trinodis** Brand and Malz, 1966; Bajocian, Germany

**G. tuscilla** Brand and Malz, 1966; Bajocian, Germany

**G. umbonata** Brand and Malz, 1966; Bajocian, Germany

**G. obtusa** Lutze, 1966; Bathonian, Germany

**G. perpolita magna** Blaszyk, 1967; Bajocian–Bathonian, Germany

**G. tuberosa angularis** Blaszyk, 1967; Bajocian–Bathonian, Germany

**G. guembelliana** (Jones) *in* Bate 1967; Bathonian, Britain

**G. oscilum** (Jones and Sherborn), *in* Bate, 1969; Bathonian, Britain

**G. persica** (Jones and Sherborn), *in* Bate, 1969; Bathonian, Britain

**G. aspera** (Khaborava) *in* Permjakova, 1970; Middle Jurassic, Dnieper Don Depression, Russia

**G. crassicostata** Permjakova, 1970; Middle Jurassic, Dnieper Don Depression, Russia

**G. losowienis** Permjakova, 1970; Middle Jurassic, Dnieper Don Depression, Russia

**G. multa** Permjakova, 1970; Middle Jurassic, Dnieper Don Depression, Russia

**G. medisculata** Blaszyk, 1972; Bajocian, Poland

**G. postercostata** Blaszyk, 1972; Bajocian, Poland

**Glyptocythere** sp. Blaszyk, 1972; Bajocian, Poland

**G. penni** Bate and Mayes, 1977; Bathonian, Britain

**Glyptocythere** sp. Bate, 1978; Bajocian, Britain

**G. raasayensis** Stevens, 1985; Bajocian, Isle of Raasay, Scotland

**G. cf. dorsicostata** Brand and Malz *sensu* Dépêche, 1985; Bathonian, France

---

**Majungaella Grekoff, 1963**

The genus *Majungaella* was described by Grekoff (1963) from the Upper Jurassic and Lower Cretaceous of the Majunga Basin, Madagascar with his new Kimmeridgian–Portlandian species, *M. perforata*, as type. He described a second new Madagascan species, *M. nematis*, ranging from the Portlandian to Valanginian. Subsequently, species of *Majungaella* have been described from the Callovian–Portlandian and Albion of Tanzania (Bate and Bayliss 1969); South Africa (Brenner and Oertli 1976; Valicenti and Stephens 1984); the Upper Cretaceous of Australia (Bate 1972); the Lower and Upper Cretaceous of Argentina (Rossi de Garcia and Prosserpio 1980; Kiellowski et al. 1983), and the Albion of the Falkland Plateau (Dingle 1984). *Majungaella aff. nematis* Grekoff is cited (not figured) from probable Valanginian strata in southern Chile (Sigal et al. 1970). According to its geographical distribution, *Majungaella* is considered to be a genus typical of the Southern Hemisphere.

In the present review, we have encountered several species which we consider would be best removed from the genus and accommodated elsewhere:

1. *M. queenslandensis* Krömmelbein, 1975 (pl. 2, figs 4–6), *M. margaritata* Krömmelbein, 1975 (pl. 1, figs 1–2) and *Majungaella* sp. A Krömmelbein, 1975 (pl. 1, fig. 3), from the Albion–Cenomanian of Australia, were recently described as the new genus *Expostercythere* Whately, Ballent and Maybury, 1995b.

2. *Majungaella*? sp. B Krömmelbein, 1975, from the Albion–Cenomanian of Australia, seems be a juvenile specimen of *Expostercythere queenslandensis* (Krömmelbein).

3. *Majungaella versera* Neale, 1975 (pl. 8, fig. 5; pl. 14, fig. 3; text-fig. 2b), from the Santonian of Australia, is placed in *Expostercythere* Whately, Ballent and Maybury, 1995b.

4. *Majungaella brentonensis* (Dingle) *sensu* Guha 1976 (pl. 3, fig. 16a–b), from the Upper Jurassic of Kutch, India, belongs to *Fastigacythere* Wiensholt.

5. *Majungaella minuta* Swain, 1976 (pl. 1, figs 19–21, 23), from the Aptian/Aibian of DSDP, north-west Atlantic, has a hemimerodont hinge and is very much smaller (L = 0.36 mm) than all other species. This is possibly a *Procycitheridea* Peterson.

6. *M. cf. queenslandensis* Krömmelbein in Dingle 1984 (figs 170–187) is conspecific with *Majungaella* sp. A Dingle, 1972 (fig. 4), from the Aptian/Aibian of South Africa, and both are included in *Expostercythere*.

7. *Majungaella* sp. 372/16 Dingle, 1984 (fig. 18a–c), from the Middle Aibian of South Africa, which seems to have an antimerodont hinge, should be referred to the Cytherideidae.
Doubtful species of Majungaella. Majungaella? hemigymnae Brenner and Oertli in Dingle 1984 (fig. 17), from the Aptian of South Africa, is only a fragmentary carapace, and it is not possible, therefore, to assign it to any genus with certainty.

Synonymized genera. In the original description by Grekoff (1963), Majungaella is diagnosed as having a robust carapace with surface coarsely punctate and an anterior marginal zone with 14–20 marginal pore canals. Dingle in Dingle and Klingler (1972) and Bate (1975) considered that these canals increase in number from 14–20 in the Jurassic, to 28–30 in the Cretaceous. Krömmlbein (1975) removed from Majungaella those Upper Cretaceous species having an increased number of anterior marginal pore canals (24–28) and a distinctive upturned postero-dorsal margin, and placed them in his new genus Tickalaracythere. Rossi de Garcia (1972) described Novocythere from the Aptian–Albian of southern Argentina, with nearly 25 anterior marginal pore canals but all other characters of her genus appear to be the same as Majungaella. We consider that an increase in number of anterior marginal pore canals is not a character sufficient to separate genera; on the contrary, it is a signal of evolution within a genus (cf. within the schulerideid lineup Eoschuleridea–Schuleridea–Aequaecytheridea). We have, therefore, amended the diagnosis of Majungaella to accommodate the species of both Tickalaracythere and Novocythere.

Stratigraphical range. Callovian to Maastrichtian.

Valid species. We consider the following species to be valid members of Majungaella:

*M. munda* (Grekoff, 1963); Middle Callovian, Madagascar (Ex Progonocythere)
*M. nematis* Grekoff, 1963; Valanginian, Madagascar
*M. perforata* Grekoff, 1963; Portlandian, Madagascar (Pl. 1, fig. 7)
*M. pyriformis* Bate and Bayliss, 1969; Albian, Tanzania
*M. annulata* Bate, 1972; Santonian and Campanian, Australia
*M. santacruziana* (Rossi de Garcia, 1972); Aptian–Albian, southern Argentina (Ex Novocythere) (Pl. 1, figs 15–16)
*M. kimmeridgiana* Bate, 1975; Kimmeridgian, Tanzania
*M. oxfordiana* Bate, 1975; Upper Oxfordian, Tanzania
*M. praepерforata* Bate, 1975; Kimmeridgian, Tanzania
*M. scheibnerovae* (Krömmlbein, 1975); Aptian–Albian, Australia. This species is probably a junior synonym of *M. santacruziana* (Rossi de Garcia)
*M. ticka* (Krömmlbein, 1975); Aptian–Albian, Australia (Ex Tickalaracythere) (Text-fig. 1A–D)
*M. bifurcata* Brenner and Oertli, 1976; Valanginian–Hauterivian, South Africa
*M. hemigymnae* Brenner and Oertli, 1976; Hauterivian, South Africa
*M. perforata* Grekoff in Guha, 1976; Upper Jurassic, India
*M. nematis* Grekoff in Guha, 1976; Upper Jurassic, India
*M. australis* Rossi de García and Proserpio, 1980; Upper Campanian–Lower Maastrichtian, southern Argentina
*Majungaella* A Kielbowicz et al., 1983; Valanginian, Southern Argentina (which we consider to be conspecific with *M. praehemigymnae* Valentici and Stephens)
*M. praehemigymnae* Valentici and Stephens, 1984; Valanginian, South Africa
*M. aitenhagenii* (Dingle) in Valentici and Stephens, 1984; Valanginian–Hauterivian, South Africa
*M. cf. perforata* Grekoff in Rosenfeld and Raab, 1984; Neocomian, Israel
Malzia Bate, 1965

The genus Malzia was described by Bate (1965, p. 110), from the Upper Bajocian of England, as Progonocytherinae with subquadrate carapace, tapering to posterior margin and with anterior and posterior compressed margins. The ventro-lateral border extended into keel-like projections and there was a low eye swelling. The hinge was entomodont, 2nd anterior dorsal pores canals numbered approximately eight.

This genus was erected with two species: the type species, Malzia bicarinata Bate (1965, p. 111, pl. 9, figs 5–8; pl. 10, figs 1–3; text-figs 11–14) having two ventro-lateral keels, and Malzia unicarinata Bate (1965, p. 113, pl. 10, figs 4–10; pl. 11, figs 1–4; text-fig. 15) with only one. Although Malzia with its keels somewhat resembles Marslatourella Malz, the resemblance is entirely superficial since the latter genus belongs to the Exophthalmocytheridae and differs in hingement and other important internal details.

Comparison of the illustrations of Malzia with those of Progonocythere yonsnabensis Bate, 1965 (p. 116, pl. 12, figs 5–14; pl. 13, figs 1–4; text-figs 16–19) and Progonocythere acuminata Bate, 1965 (p. 114, pl. 2, figs 5–10; pl. 12, figs 1–4), both from the Bajocian of England, shows that Malzia is merely Progonocythere with ventro-lateral keel-like projections. The amended diagnosis of Progonocythere (see above) includes Malzia.

Fastigatocythere Wienholz, 1967

This genus was based mainly on species with inverted chevron-type ornament, pronounced postocular sulcus and entomodont hinge. In addition to the type species, F. rugosa from the Callovian of north-west Germany, and Progonocythere juglandica juglandica (Jones) from the Middle Jurassic of Europe, Wienholz (1967) also included the following Middle Jurassic Madagascan species of Grekoff (1963): Progonocythere acissa, P. bicruca, P. befoetakaensis, Progonocythere 2393 and P. juglandica malgachica. Since 1967, there have been many more records of the genus. In our opinion, those which follow should be excluded.

1. Lophocythere interrupta Triebel, 1951 (pl. 47, figs 35–41) from the Callovian of Europe, has been placed by a number of authors in Fastigatocythere. However, we agree with Whatley (1970, p. 335) that it conforms to the diagnosis of Lophocythere Sylvester-Bradley and should certainly be retained there.
2. Dépéche (1973, p. 216) reclassified Fastigatocythere to the position of Progonocythere Lophocythere Sylvester-Bradley but we retain it here as a distinct genus. Both Lophocythere (Fastigatocythere) bestnensis Dépéche, 1973, pl. 1, figs 5–8 and Lophocythere (Fastigatocythere) rimosa Dépéche, 1973, pl. 1, figs 9–13, from the Lower Bathonian of France, belong to our opinion, to Neurocythere Whatley.
3. Fastigatocythere? grekoffi Brenner and Oertli, 1976 (pl. 6, fig. 5–12; pl. 8, fig. 6), from the Valanginian of South Africa, is certainly Majungaella Grekoff.
4. Fastigatocythere interrupta interrupta (Triebel, pl. 4, figs 5–6) and F. interrupta subsp. A (Lutze), pl. 4, figs 8–9, both in Herngreen et al. (1983–1984), from the Middle Callovian of the eastern Netherlands should be retained in Lophocythere Sylvester-Bradley. (See 1. above).
5. Fastigatocythere nautilisensis Rosenfeld and Raab, 1984 and Rosenfeld et al. 1988, from the Lower Cretaceous of Israel, seems to have an anteromodal hinge and possibly belongs to Neurocythere Merens.

Doubtful species of Fastigatocythere. Fastigatocythere? sp. Neale and Singh, 1985 (pl. 2, fig. 11), from the Oxfordian of India, is particularly difficult to place generically due to the inadequacy of its illustration.

Synonymized genera. The diagnosis of Fastigatocythere is herein amended to accommodate the species of Amicytheridea Bate; Glyptogatocythere Basha; and Zerqacythere Basha.
Emended diagnosis of Fastigatocythere Wienholz, 1967. Progonocytherinae with subtriangular to subrectangular lateral outline; ornamented by ribs in inverted chevron which overreach dorsal margin and may be broken up centrally into coarse reticulation creating prominent tubercles. Ventrally punctate or with ribs parallel to ventral margin. Eye tubercle and marked post-ocular sulcus. Left valve larger than right. Anterior marginal pore canals normally seven to nine, but range up to 14. Avestilulate. Frontal scar anterodorsal in position, usually circular.

Distribution. Fastigatocythere Wienholz is a typical Middle and Upper Jurassic genus with a wide stratigraphical and geographical distribution. In the Northern Hemisphere, it has been recognized mainly from the Bathonian–Kimmeridgian of Britain, continental Europe, Egypt, Jordan and Saudi Arabia; it is also recorded (not illustrated) from the Callovian and Oxfordian of offshore eastern Canada (Ascoli 1988, p. 26). In the Southern Hemisphere, it is recognized from the Bathonian–Kimmeridgian of East and South Africa, Madagascar and India, and also from the Lower Bajocian of Australia. From the Middle Callovian of Argentina, there is one species.
(Progonocythere nequenensis Musacchio) which, at present, we assign tentatively to Fastigacythere Weinholz.

Valid species. We consider the following species to be valid members of Fastigacythere:

F. rugosa Weinholz, 1967; Lower Callovian, Germany
*F. accessa* (Grekoff, 1963); Bathonian–Callovian, Madagascar (Ex. Progonocythere)
*F. bicruicata* (Grekoff, 1963); Bathonian–Callovian, Madagascar (Ex. Progonocythere)
*F. befoatauenensis* (Grekoff, 1963); Bathonian–Callovian, Madagascar (Ex. Progonocythere)
*Fastigacythere* 2393 (Grekoff, 1963); Bathonian–Callovian, Madagascar (Ex. Progonocythere)
*F. juglandica juglandica* (Jones) in Wienholz, 1967; Middle Jurassic, Europe and Madagascar (Pl. 1, figs. 10–14)
*F. juglandica malgaica* (Grekoff, 1963); Bathonian–Callovian, Madagascar
*F. aff. brentonensis* (Dingle) in Bate, 1975; Middle–Upper Kimmeridgian, Tanzania
*F. ihopensis* (Grekoff) in Bate 1975, Bathonian–Callovian, East Africa, India and Madagascar (Ex. Amicytheridea) (pl. 1, fig. 17)
*F. triangulata* (Bate, 1975); Callovian, East Africa and Madagascar (Ex. Amicytheridea)
Fastigacythere sp. Guha; 1976, Bathonian, India
F. accessa (Grekoff); in Guha, 1976, Upper Jurassic, India
Lophocythere (Fastigacythere) aff. juglandica (Jones) in Rohr, 1976; Bathonian, southern France
*F. maltzi* (Basha, 1980); Bathonian, Jordan and Egypt (Ex Glyptogacythere)
*F. naftalianis* Rosenfeld and Raab, 1984; Neocomian, Israel
Fastigacythere sp. Dépêché, 1985; Middle Bathonian, France
*F. bakeri* (Basha) in Rosenfeld et al., 1987; Bathonian, Egypt
*F. oblonga* (Dépêché; Le Hindre, Manivit and Vaslet, 1987); Middle Callovian, Saudi Arabia (Ex. Amicytheridea)
*F. dieralaisensis* (Basha, 1980) form A Dépêché et al., 1987; Bajocian, Saudi Arabia (Ex. Amicytheridea)
*F. dierallaensis* (Basha, 1980) form B Dépêché et al., 1987; Upper Callovian, Saudi Arabia (Ex. Amicytheridea)
*F. dhrumaensis* (Dépêché, Le Hindre, Manivit and Vaslet, 1987); Bajocian, Saudi Arabia (= Glyptogacythere magharaensis Rosenfeld and Gerry in Rosenfeld et al., 1987) (Ex. Amicytheridea)
*F. triangula (sic)* (Bate) in Dépêché et al., 1987; Upper Callovian, Saudi Arabia (Ex. Amicytheridea)
F. juglandica (Jones) Brand 1990; Upper Bathonian, north-west Germany
F. grossepunctata (Chapman) in Malz and Oertli, 1994; Lower Bajocian, Australia
F. suboblonga (Basha, 1980); Bathonian, Jordan, Egypt and Saudi Arabia (Ex. Zergacythere)
F. huneinis (Basha, 1980, pl. 4, figs 12–14); Bathonian, Jordan (Ex. Zergacythere); herein given the new name Fastigacythere jordancea. This is necessary because Basha gave both a Glyptogacythere species and a Zergacythere species the name huneinis. Since we have decided that both belong to Fastigacythere, one must be given a new name.
F. magharaensis (Rosenfeld and Gerry in Rosenfeld et al., 1987); Bajocian, Egypt
Fastigacythere sp. Khosla and Jakhara, 1994 (fig. 4, 6–8); Upper Bathonian–Callovian, Kutch, India

Novocythere Rossi de García, 1972

The genus Novocythere was described by Rossi de García (1972, p. 271, pl. 1, fig. 7), from the Aptian–Albian of well SC-1, southern Argentina, with *N. santacruzanica* as type species. According to the original description, the genus is pyriform, postero-dorsally upturned, strongly convex in dorsal view and ornamented by concentric puncta. Marginal denticles are present and the hinge is entomodont. The vestibulum is small and there are nearly 25 marginal pore canals anteriorly.

The same author (1977, p. 117, pl. 1) re-illustrated the genus using SEM and pointed out some further aspects of the morphology and age of Novocythere. At the same time, she differentiated it from Majungaella Grekoff and Tickalaracythere Krömmleniein on the basis of its lack of an eye tubercle and presence of an anterior vestibulum. However, her illustrations show that the type material has a low elongate ocular swelling which we interpret as an eye tubercle. With reference to the vestibula, no mention is made of this feature in the type description of Majungaella and, ironically, Majungaella australis Rossi de García and Proserpio, 1980 clearly shows a narrow anterior vestibulum. In the absence of any morphological criteria to separate this monospecific genus from Majungaella, we subsume it herein as a junior synonym.
Amicytheridea Bate, 1975

This genus, from the Middle Callovian of Tanzania, East Africa, was erected by Bate (1975) with Procytheridea ihopensis Grekoff, 1963 as type species. A. triangulata Bate = Procytheridea? 3330 Grekoff, 1963, also from the Middle Callovian of East Africa, was also designated.

As diagnosed by Bate (1975, p. 91), Amicytheridea has a robust carapace, triangular in lateral outline and convex in dorsal view, with dorso-lateral ribs in an inverted chevron. The left valve is larger than the right. The eye tubercle and oblique post-ocular sulcus are clearly marked. The hinge is lobodont (with antero-median element loculate in the right valve). The anterior marginal pore canals number approximately 14.

Although he claimed that the hinge of Amicytheridea is lobodont, it can be seen (Bate 1975, p. 193, fig. 11a–c) to be also entomodont. In fact, the difference between the two hinge types is only a matter of degree; in the lophodont hinge, the denticles on the antero-median element of the left valve are more distally expanded than in an entomodont hinge. We would not regard this as a generic character. In our opinion, Amicytheridea is synonymous with Fastigatocythere Wienholz, mainly because of its subtriangular shape, dorso-lateral inverted chevron ornament, ventro-lateral ribs parallel to the ventral margin, and clear eye tubercle and post-ocular sulcus. The antennal scar, however, is situated antero-centrally.

The emended diagnosis of Fastigatocythere (see above) includes Amicytheridea whose species are transferred and listed thereunder.

Tickalaracythere Krömmelbein, 1975

The genus Tickalaracythere was defined by Krömmelbein (1975) with two species, T. ticka (the type) and T. scheibnerovae, both from the Albian–Cenomanian of the Great Artesian Basin, Queensland, Australia. It has also been cited but not illustrated from the Campanian–Maastrichtian of the Sergipe Basin, eastern Brazil (Krömmelbein 1976, p. 546).

Krömmelbein (1975) erected this genus to separate from Majungaella some Upper Cretaceous species with robust and trapezoid-pyiform carapaces, which were postero-dorsally upturned, strongly convex in dorsal view, ornamented by a concentric pattern of punctations, with eye tubercle, shallow post-ocular sulcus and marginal denticles. Their hinges are entomodont, anterior pore canals range in number from 24 to 28, and an anterior vestibulum is present in males. We believe these characters, in the context of the total range of characters within the plexus of Majungaella and Tickalaracythere, to be specific and not generic. Consequently, we regard Tickalaracythere as a junior synonym of Majungaella and have emended the generic diagnosis of the latter accordingly (see also Whatley et al. 1995a). Species previously assigned to Tickalaracythere are accordingly transferred, and listed under Majungaella (see above).

Glyptogatocythere Basha, 1980

The genus Glyptogatocythere was erected by Basha (1980, p. 241) with G. malzi, from the Bathonian of Jordan, as type species. Rosenfeld and Gerry in Rosenfeld et al. (1987, p. 260) described a second species, G. magharaensis, from the Bajocian of Egypt. As diagnosed, Glyptogatocythere Basha is subtriangular, ovate, centrally inflated in a triangular form; it is ornamented by subtriangular ribs in an inverted chevron with marked eye tubercle and oblique post-ocular sulcus. The left valve is larger than the right. The hinge is entomodont.

According to the type description and illustrations of Glyptogatocythere, we consider it to be synonymous with Fastigatocythere Wienholz, and its species are transferred.

Zerucythere Basha, 1980

Basha (1980, p. 251) first described the genus with Z. subiehiensis as type species and with another new species, Z. huniensis; both came from the Bathonian of Jordan.
As diagnosed, this genus has a subtriangular carapace with a surface ornamented by sub-triangular ribs, in an inverted chevron, which overreach the dorsal margin and develop into complicated reticulation supported by two to three prominent, raised tubercles; the eye tubercle is prominent and there is a pronounced oblique post-ocular sulcus. The hinge, while allegedly lobobont, is clearly entomodont.

We consider that Zerqacythere is merely Fastigatocythere in which the ribs are broken up centrally into coarse reticulation creating prominent tubercles. We have, therefore, placed the two species of Zerqacythere within Fastigatocythere and consider the genus as a junior synonym. The emended diagnosis of Fastigatocythere Wienholz (see above) includes Zerqacythere, whose species are listed thereunder.

**Dromacythere Ware and Whatley, 1980**

This genus was separated by Ware and Whatley (1980) from its apparent closest relative, *Fastigatocythere* Weinholz, 1967. Named for its 'humped' dorsal margin, *Dromacythere* differs from *Fastigatocythere* and from other progonocyontherids in its small size (0.41–0.48 mm adult length), exceptionally strongly developed entomodont hinge and the very strongly developed eye tubercle. *Arkellicythere* Ware and Whatley, 1980 is also small but has many more radial pore canals (18–22 anteriorly as opposed to eight anteriorly in *Dromacythere*). It was originally thought to be a progonocyontherid but re-examination of its hinge has shown it to be antimerodont and the genus is, thereby, excluded from the family. It is possibly a protocytherid.

*Dromacythere sagitta* Ware and Whatley, 1980 (Text-fig. 1f–hi) is the type and only known species of the genus, which does not seem to be particularly close to the other genera in the complex we have considered here. The following generic diagnosis is after Ware and Whatley, 1980. Small, subquadrate to globose, dimorphic, ornamented, progonocyontherid, dorsally umbo-nate, with an eye tubercle and prominent post-ocular sinus. Radial pore canals few, straight, widely spaced. Hinge strongly entomodont, muscle scars type A (Bate 1963). Monotypic.

**Strictocythere Sheppard in Brand, 1990**

The genus *Strictocythere* was introduced by Sheppard (1981, p. 59) in her unpublished doctoral thesis to accommodate a group of species previously assigned to *Progonocythere*. Brand (1990, p. 207) used this name under the authorship of 'Sheppard in Brand'. Brand differentiated two subspecies from the type species *Progonocythere polonica, S. polonica polonica* (Blaszky) and *S. polonica recta* Brand, both of them from the Upper Bathonian of north-west Germany (Brand 1990, pl. 13, figs 8–15 and figs 16–21 respectively). Malz and Oertli (1994, pl. 1, figs 4–5) described *‘Strictocythere prolongata’* (nom. nov. pro *Loxoconcha elongata* Chapman, 1904) from the Lower Bajocian of Australia.

As diagnosed by Sheppard (1981) and emended by Brand (1990), *Strictocythere* is elongate-oval in shape, with anterior and posterior compressed margins, well rounded anterior margin and rounded triangular posterior margin with a short caudal process. The ventro-lateral border of valves slightly overhangs the ventral margin; the ornament is pitted and the hinge is entomodont.

We consider that *Strictocythere* is merely *Progonocythere* with elongate-oval lateral outline. Our emended diagnosis of *Progonocythere* incorporates the species of *Strictocythere* Sheppard in Brand and the genus is, thereby, subsumed.

**Acknowledgements.** RCW acknowledges the agreement between the Royal Society and the Argentinian Science and Technology Research Council (CONICET) which allowed him to work on this paper in the Museo de La Plata, and SB thanks the EEC for the bursary which allowed her to spend six valuable months in Aberystwyth. Both authors are indebted to Drs J. E. Whittaker, M. Ayress, I. P. Wilkinson and T. Jelineck respectively of The Natural History Museum, London, the Australian National University, the British Geological Survey, and the Senckenberg Museum, for SEM photographs of primary types or the loan of specimens. We acknowledge the kindness of Dr N. Malúnián of the Dirección Nacional del Servicio Geológico, Buenos Aires, for allowing
us access to the Ostracoda housed in the collections of that institution. We thank Dr Basha of Jordan for negatives of taxa described by him. We thank Dr Ian Boomer (IES) for carefully reading an earlier version, and Dr R. H. Bate, whose trenchant criticisms and his discovery of important errors were very welcome. The opinions expressed in the paper, however, are entirely our own. We thank Dr Alicia Mogulevsky and Lic. Alfredo Benialgo who both helped in many ways. Lastly, many thanks to the photographic service of the IES, Aberystwyth for their considerable endeavours on our behalf.
